Comment on “Two Time Scales and Violation of the Fluctuation-Dissipation Theorem in a Finite Dimensional Model for Structural Glasses”

In a recent paper, Ricci-Tersenghi et al. [1] show that, in the frustrated Ising lattice gas (FILG) [2], the fluctuation-dissipation relation between density-density correlations and associated responses, following a quench in the chemical potential, is characterized by two linear regimes, with a piecewise constant fluctuation-dissipation ratio (FDR). The authors take the value \( \beta J = 10 \) of the coupling between particles, and quench the system from a low value of \( \beta \mu \), in the liquid phase, to \( \beta \mu = 10 \), deep in the glassy phase. After a waiting time \( t_w \) they apply a small random perturbation in the chemical potential, and measure the correlation \( C(t_w, t) \) and the integrated response \( T\kappa(t_w, t) \). For \( t - t_w \ll t_w \) they find the linear FDT regime \( T\kappa(t_w, t) = 1 - C(t_w, t) \), and for \( t - t_w \geq t_w \) the linear out of equilibrium regime \( T\kappa(t_w, t) = (1 - q_{EA}) + X(q_{EA} - C(t_w, t)) \), with \( X = 0.64(3) \) and \( q_{EA} = 0.92(1) \). We have repeated the experiment for size \( 32^3 \), taking this time for convenience the value \( \beta J = \infty \) and quenching to the same value \( \beta \mu = 10 \), with \( t_w = 10^5 \) and a perturbation \( \beta \epsilon = 0.1 \). The result is shown in Fig. 1 (circles): it is definitely not reached the equilibrium values. Indeed the latter may suffer from a number of problems, for example that at \( t_w \) one time observables have not yet reached the equilibrium values.

We have checked the thermalization of the system looking for the density overlap of the FILG, to the distribution \( P(q) \) plotted in Fig. 2. The dotted line is \( 1 - x \).

It has been recently proved [3] that, for systems in which the free energy density tends asymptotically to the equilibrium one, and in which the stochastic stability holds, the FDR function \( X(q) \) is connected to the equilibrium overlap distribution \( P(q) \). The piecewise constant FDR found in Ref. [1] would then correspond, for the density overlap of the FILG, to the distribution \( P(q) = X\delta(q - q_{\text{min}}) + (1 - X)\delta(q - q_{EA}) \), where \( q_{\text{min}} = C(t_w, t) \). We have measured \( P(q) \) on a system of size \( 10^3 \) using the Parallel Tempering technique, with \( \beta J = \infty \) and 25 chemical potentials between \( \beta \mu = 1 \) and \( \beta \mu = 10 \), averaging over 32 disorder configurations. We have checked the thermalization of the system looking at the asymmetry of the spin overlap distribution. In Fig. 2 we show the result for \( \beta \mu = 10 \) (solid line), together with the two delta functions corresponding to the FDR of Ref. [1]. Of course for finite size the delta functions will be smeared out, and one must expect two non-zero width peaks, but also taking this in account the two distributions are definitely different. For a crossed check, in Fig. 3 we plot the function that would correspond to the equilibrium \( P(q) \) (solid line): it is definitely not compatible with the measured \( T\kappa(t_w, t) \) versus \( C(t_w, t) \).

It is important to point out that the overlap distribution \( P(q) \) shown here has been measured using a particularly efficient algorithm, and taking care that the system had indeed thermalized. Therefore we believe that the susceptibility deduced from the \( P(q) \) is more reliable than the one measured in the off-equilibrium experiment.

FIG. 1. Circles: response versus correlation for size \( 32^3 \), \( \beta J = \infty \) and \( \beta \mu = 10 \). Dashed straight line: same fit of Ref. [1]. Solid line: function corresponding to the equilibrium \( P(q) \) plotted in Fig. 2. The dotted line is \( 1 - x \).

FIG. 2. Solid line: equilibrium distribution \( P(q) \) for size \( 10^3 \), \( \beta J = \infty \), \( \beta \mu = 10 \). Vertical bars: function \( X\delta(q - q_{\text{min}}) + (1 - X)\delta(q - q_{EA}) \) with the same \( X \) and \( q_{EA} \) of Ref. [1].
